32 Channel Simultaneous Analog Output Card AO32CPCI-ER

AO32CPCI Simultaneous Analog Output Specification

32 Channels Simultaneous AO 500k Sample per Second per Channel 18-bit DAC Device per channel Simultaneous Update -ERB model available with improved accuracy.

Internal, External Clock selection Internal, External Trigger selection Optional 64 bit Digital Output DO Optional Clocked DO Operating modes, for both AO and DO functions - Register, - Arbitrary Waveform Generator AWG - Low Latency

6U CompactPCI peripheral mode Data Acquisition Board. PXI backplane clock and trigger routing. Support for multiple board synchronisation

Description

AO32CPCI-ER provides simultaneous Analog Output (AO) and Digital Output (DO) expansion for CPCI systems. The card provides enhanced signal resolution over the standard AO32CPCI.

AO32CPCI offers substantial performance improvement on RTM-AO16. For AO and DO, there is a FIFO driven AWG function, capable of operating continuously up to 1MHz. ACQ196 is able to drive the AO32 AWG and its own local AI capture concurrently at rates over 100kHz. A single ACQ196CPCI in system slot mode can control up to 7 AO32CPCI cards in a standard chassis.

The AO, DO functions maybe be triggered externally. The card features two separate clock counters, and the both functions may be clocked either by an internal clock, external clock or external divided clock. Clocks and Triggers may be input on the front panel, and/or shared on the PXI-compatible backplane. Apart from AWG applications, the card also allows simple registerper-channel update as well as efficient single cycle low latency update by the general purpose

EPICS IOC device support.

Applications:

Precision Control Applications.

Networked control system elements.

Power Supply control.

Automatic Test Systems.

General purpose AWG applications.

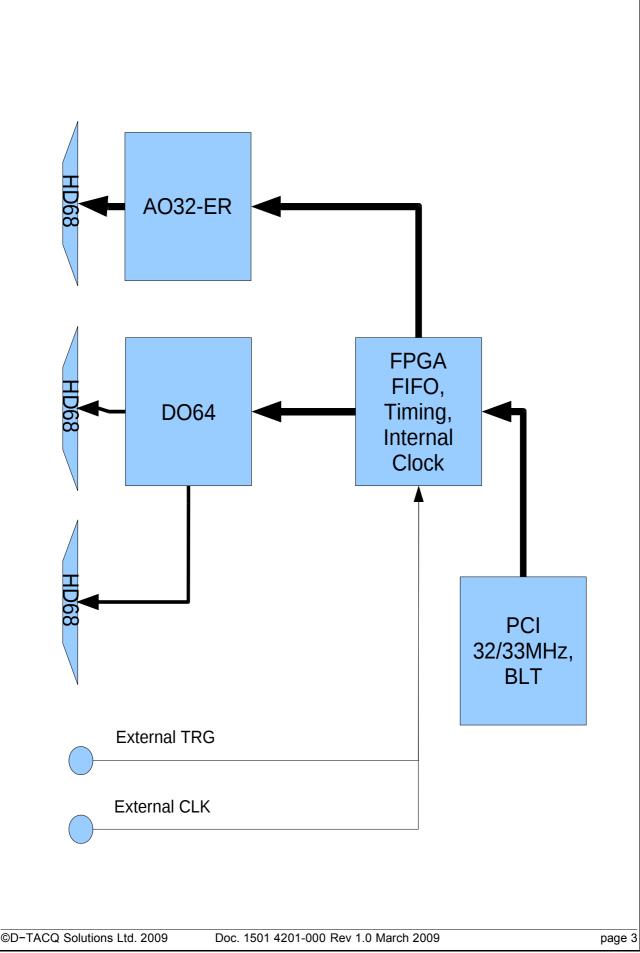

Sonar simulation/stimulation.

Part Number	AO	DO	Comment

Registered Operation

Each AO channel is mapped to a 32 bit individually addressable register. The DO64 word is mapped to two 32 bit individually addressable register. Output may is updated on software or optional hardware trigger

AWG Operation

All the AO channels are fed with data from a single FIFO buffer.

All the DO channels are fed with data from a separate FIFO buffer.

Host side software services each FIFO, and AO, DO functions may be clocked at different rates.

AO, DO functions are clocked, choice of external front panel, external PXI or internal clocks.

The AO, DO clock inputs each have a programmable divide allowing different rates to be set from a common clock.

Low Latency Operation

In this case, both AO and DO are fed with data from the same FIFO buffer. The FIFO buffer is optimised to transfer data immediately on first sample. The combination of single block write cycle for both AO, DO, and the immediate buffer update is designed for lowest possible latency output.

Example System Configuration:

Networked controller: 1U CPCI chassis, 2 slot, 1 x ACQ196CPCI-96, 96 channels in networked appliance mode. 1 x AO32CPCI-64DO : 32 AO, 64DO in AWG mode. Typically the ACQ196CPCI will operate as a network controller node running as an EPICS IOC. ATE System: Server class Pentium system connects to: 2U CPCI chassis, 4 slot: 1 x PCI bus extender in system slot 1 x ACQ196CPCI-96 in slot 2 2 x AO32CPCI-ER-DO64 in slots 3, 4. Here a dedicated algorithm runs on the Pentium. ACQ196 is responsible for transferring data from Pentium host memory to the AO32 devices, and to deliver acquired data direct to the Pentium memory. Sonar Simulation/Stimulation system: 4U CPCI chassis, 8 slot 1 x ACQ196CPCI-96 in system slot 7 x AO32CPCI in peripheral slots 220 channel audio output system. May be used to test large systems based on ACQ196CPCI. D-TACQ Solutions Ltd.
